ABSTRACT

Objectives: Contrasting accounts exist on whether people with stroke are able to self-report on outcomes using visual analogue scales (VASs). We explored correlations between multi-item scale-rated health-related quality of life (HRQL) and VAS-rated HRQL after stroke, and compared those with versus without aphasia.

Design: Cross-sectional survey.

Setting: Community dwelling stroke patients living in London.

Participants: People with first stroke were recruited during their hospital stay and were assessed 3 months later.

Measures: The Frenchay Aphasia Screening Test, the Stroke and Aphasia Quality of Life Scale (SAQOL-39g) and a single vertical VAS.

Results: 73 people took part, 14 with aphasia. VAS scores were significantly correlated with the overall SAQOL-39g ($r=0.69$, $p<0.01$). SAQOL-39g subdomain scores were also correlated with VAS scores, with the psychosocial domain most highly correlated ($r=0.67$, $p<0.01$) and the communication least correlated ($\rho=0.30$, $p<0.05$). SAQOL-39g—VAS difference scores were higher for people with aphasia and the difference was significant ($t(71)=2.02$, $p<0.05$).

Conclusions: Despite the significant correlation of the overall SAQOL-39g and the VAS-rated HRQL, subdomain results suggested that people considered mostly psychosocial aspects when rating their HRQL on a single VAS. Agreement was poorer for people with aphasia, raising issues for the use of VASs with people with aphasia.

INTRODUCTION

Health-related quality of life (HRQL) reflects the impact of a health state, here stroke, on a person's ability to lead a fulfilling life. It covers an individual's perception of and satisfaction with their physical, mental/emotional, family and social functioning.¹ In stroke, an overarching rehabilitation aim is to improve each person's sense of well-being and quality of life.²

The simplest way to measure HRQL is through a single question or single-item measure. Such measures have an obvious

ARTICLE SUMMARY

Strengths and limitations of this study

- Study findings do not support the use of visual analogue scales as outcome measures for people with aphasia.
- Their scope is limited compared with multi-item measures.
- Of the 73 people who took part in the study, only 14 had aphasia. Findings need to be replicated in a larger study.

advantage: they are easy to administer and complete and thus less burdensome for clients and more efficient in terms of time and resources. One type of a single-item measure is a visual analogue scale (VAS) which typically comprises a 100 mm long line anchored at the ends with opposing states of a construct (eg, best possible and worst possible HRQL). In stroke, where people may have aphasia (difficulty communicating due to impaired understanding and use of language) or cognitive impairment, VASs seem particularly pertinent.

However, VASs and other single-item measures are unlikely to cover the broad scope of a complex construct, like HRQL; they may be interpreted in different ways by respondents; they cannot discriminate to a fine degree between different levels of an attribute and they tend to have limited reliability (prone to random error) as they do not produce consistent answers across time.^{3 4} For these reasons, HRQL is typically measured with multi-item scales. Multi-item scales have more items which increase the scope of a measure; they are less open to variable interpretation; they are more precise and they are more reliable by allowing random errors to average out.^{3 4}

In stroke, multi-item scales have been developed for the assessment of HRQL, yet only a few have been tested with people with aphasia.^{5–7} The Stroke and Aphasia Quality of Life scale (SAQOL-39g) has been adapted for use specifically with people with aphasia,

with strong results on its reliability, validity and sensitivity to change in people with and without aphasia post-stroke.^{6–8} It comprises 39 items covering physical, psychosocial and communication subdomains.

Despite the methodological limitations of VASs identified above, their apparent simplicity makes them attractive outcome measures for people with stroke. They have been successfully used to measure mood and self-esteem in stroke.^{9–10} However, Pickard *et al*¹¹ compared five different ways of measuring HRQL after stroke and found that a VAS was the most difficult to use without assistance and the least responsive to change.

This study had two aims (1) to explore how a single VAS on HRQL correlated with an established multi-item HRQL scale (SAQOL-39g) in people with stroke and (2) to see if there was a difference between people with aphasia and those without on agreement between VAS and SAQOL-39g scores.

METHODS

Design and participants

This study was part of a larger longitudinal study that assessed quality of life and emotional distress following stroke.^{12–13} All participants gave written informed consent. Participants had to be: over the age of 18; admitted with a first stroke and requiring a stay of at least 3 days in the hospital. Exclusion criteria and full sample details are provided in the previous reports.^{12–13} For this study, participants were those of the original cohort ($n=87$) who completed the required measures (see below) at 3 months poststroke ($n=73$).

Measures

Participants completed the Frenchay Aphasia Screening Test (FAST)¹⁴, the SAQOL-39g⁷ and a vertical VAS on their HRQL. The FAST is a screening tool to determine the presence of aphasia, with good evidence of reliability and validity. To take part in the study, people had to score a minimum of 7/15 on the receptive domains of the FAST, to ensure that they could understand the questions of the SAQOL-39g⁷. The SAQOL-39g consists of 39 items that cover people's evaluation of their functioning in three domains: physical (eg, 'How much trouble did you have doing daily work around the house?'), psychosocial (eg, 'Did you feel discouraged about your future?') and communication (eg, 'How much trouble did you have getting other people to understand you?'). Overall and subdomain mean scores range from 1 to 5; higher scores indicate better HRQL. The VAS comprised a 100 mm vertical line anchored at the bottom by zero and the statement 'worst imaginable quality of life after stroke' and at the top by 100 and the statement 'best imaginable quality of life after stroke'. Participants were asked to look at the line and think about how their quality of life was affected by their stroke. There were small lines along the line at each centimetre interval and participants had to mark where they felt they were.

RESULTS

Respondent characteristics

Seventy-three people took part, 14 (19%) were aphasic. Most (88%) had an ischaemic stroke and most common type was partial anterior circulation stroke (32%). The majority were white (74%), men (58%) and married/had a partner (55%). They ranged in age 18–91 (mean (SD)=69.7(14)).

Correlations between SAQOL-39g scores and VAS ratings

Table 1 presents scores on the VAS and the SAQOL-39g. They were normally distributed except for the SAQOL-39g communication subdomain. Comparing people with aphasia to those without, their scores were lower and more spread out both on the VAS (mean (SD)=57.64 (30.12) versus those without aphasia: 69.32 (21.98)) and the SAQOL-39g (mean (SD)=3.27 (0.74) vs 3.97 (0.69) of those without aphasia) and its subdomains.

Table 2 and figures 1–3 present correlations between VAS ratings and SAQOL-39g scores for the overall sample and the two subgroups (aphasia vs no aphasia). Correlations between the VAS ratings and SAQOL-39g overall, psychosocial and physical domains were moderate-to-high ($r=0.40$ – 0.81) and significant (for 8/9 $p<0.01$). Despite this, the scatterplots reveal a more complex picture. Though they showed a positive somewhat linear trend, the points were quite scattered, especially on the VAS with SAQOL-39g physical domain, suggesting a weak association. There were also two outliers (from the subgroup of people with aphasia) who scored 0 on the VAS despite their scores on the SAQOL-39g. Correlations between the VAS and the SAQOL-39g communication subdomain were lower than for the other domains ($p=0.17$ – 0.30 ; $r=0.39$). The scatterplots were quite spread out and as expected showed ceiling effects on the SAQOL-39 communication domain for the overall sample and those without aphasia.

Comparisons between people with aphasia and those without on agreement between VAS and SAQOL-39g scores

To see if there was a difference between people with aphasia and those without on agreement between SAQOL-39g and VAS, difference scores (SAQOL-39g—VAS) were calculated, after converting VAS ratings and overall SAQOL-39g scores into standard scores. Difference scores (mean(SD)) of aphasic participants (-0.37 (0.74)) were greater than those of participants without aphasia (0.10 (0.79)), and the difference was significant ($t(71)=2.02$, $p=0.047$). The negative values of the scores of people with aphasia show they rated their HRQL higher with VAS than with SAQOL-39g. The opposite was true for those without aphasia.

DISCUSSION

The high and significant correlations between the SAQOL-39g and the VAS may seem to suggest that in a

Table 1 Descriptive statistics of participants' scores on the VAS and the SAQOL-39g

	VAS	SAQOL-39g			
		Overall	Physical	Psychosocial	Communication
All (n=73)

SAQOL-39g, Stroke and Aphasia Quality of Life Scale; VAS, visual analogue scale.

generic stroke sample a single VAS may yield similar findings on HRQL as a multi-item scale. However, the correlations between SAQOL-39g subdomains and the VAS showed that some aspects of those covered in the SAQOL-39g, that is, psychosocial, contributed more in the VAS ratings than others. Similar findings have also been reported by Pickard *et al*¹¹ where, of five measures of HRQL, the VAS was most strongly associated with depression scores.

It is not surprising that in the overall sample the communication subdomain was least correlated with the VAS rating. The majority of the sample did not have aphasia and therefore communication would be expected to contribute less to HRQL than psychosocial and physical factors. However, for participants with aphasia, results were not as expected: VAS ratings were not significantly correlated with SAQOL-39g communication scores. This may suggest that people with aphasia were not thinking of communication when they rated their HRQL on a VAS. If this is the case, then VASs are less valid than multi-item scales in assessing HRQL.³ In a recent

systematic review of predictors of HRQL for people with aphasia, the importance of communication was highlighted, as communication disability was one of the strongest predictors.¹⁵ Our findings suggest that multi-item scales, such as the SAQOL-39g, prompt respondents to think about a wider variety of contributing factors to HRQL than a single VAS can do.

Looking at VAS—SAQOL-39g agreement, people with aphasia had significantly lower agreement scores. They also used VASs differently to those without aphasia: they rated their HRQL more highly on a VAS, whereas those without aphasia rated their HRQL more highly on the SAQOL-39g. We explored whether other factors such as age and gender may have contributed to this difference, as, for example, older people may have greater difficulty in responding to VASs.¹⁶ We found no significant differences in demographic characteristics between people with aphasia and those without.

It is a limitation of the study that only 14 participants (19%) had aphasia. Moreover, a fuller assessment of the sample's cognitive and communication deficits may have provided more information on how stroke survivors use VASs. These limitations notwithstanding, our findings have important clinical implications. In clinical practice, VASs are often used especially with people with aphasia, despite their limitations as assessments and outcome measures^{3, 4} because they are considered easy and accessible. This is problematic. VASs may provide a quick impression of HRQL but their scope is limited. Our study confirmed existing research that multi-item scales cover the broad construct of HRQL more comprehensively, whereas VASs reflect more psychosocial factors.¹¹ Additionally, we showed that people with aphasia use VASs differently than other people with stroke; and had greater discrepancies between their VAS-rated and SAQOL-39g-rated HRQL. Valid and reliable multi-item scales should therefore be the tool of choice to assess HRQL in people with stroke and aphasia.

Table 2 Correlations between VAS ratings and SAQOL-39g scores

SAQOL-39g	VAS		
	Total sample	By aphasia	
	N=73	Non-aphasic n=59	Aphasic n=14
Overall	0.69**	0.64**	0.81**
