CONTINUED VALUE CREATION IN CROWDSCOURING FROM
CREATIVE PROCESS ENGAGEMENT

Abstract

- Purpose

Crowdsourcing delivers creative ideas for the issuing firm, but participants’ engagement in the creative process also creates additional benefits to firms and participating customers. To investigate if these spill-over values endure over time, this study uses data from two time points, i.e. at submission and after announcement of the contest winners, to investigate the relationship between the degree of a participant’s creative process engagement (CPE) and value creation from a crowdsourcing contest, and how these perceptions of value change over time.

- Design/methodology/approach

Data was collected from 154 participants in a crowdsourcing contest at two time points with an online survey: at submission, and after receiving feedback (in term of rankings, rewards, and comments) from the community. Partial Least Square (PLS) path modelling was used to estimate both main and moderating effects.

- Findings

CPE increases the perceived value of customers (social and epistemic value) and firms alike (knowledge-sharing intention and customer loyalty), though all but epistemic value decrease over time. Disconfirmation of expectations and need for recognition moderate these effects.

- Originality/value

This paper is the first longitudinal study that helps understanding the effect of CPE on value creation from crowdsourcing across time. It also uses the theoretical lens of the honeymoon hangover effect to explain how perceived value changes. The resulting insights into the role of customer engagement in crowdsourcing contests and subsequent value creation will be beneficial to the growing research stream on consumer value co-creation and user innovation.

Keywords: Crowdsourcing, Creative process engagement, Value creation, Disconfirmation of expectation, Need for recognition
Introduction

Crowdsourcing is a problem-solving and production platform that enhances customer engagement and value creation (Yang et al., 2008) by using the collective intelligence of networked communities (Piller, 2008). Crowdsourcing tasks range from simple to highly complex. Leading firms such as Coca Cola, DELL, and P&G have outsourced complex tasks which demanded a higher level of cognitive capability, and required more effort in the problem-solving process, than a typical crowdsourcing activity (Dontcheva et al., 2011, Howe, 2009, Poetz and Schreier, 2012). For example, Cisco launched a billion-dollar global idea competition named Cisco I-Prize, calling for innovative ideas on technologies and markets to help Cisco widen its business scope. In 2010, Cisco invited entrepreneurs, innovators, students and technologists to submit new business ideas. The winning team earned $250,000. More than 2,900 participants from 156 countries submitted 824 ideas to the contest (Roth, 2012).

Crowdsourcing plays an important role in service innovation (Ye and Kankanhalli, 2013, Mladenow et al., 2014, Ordanini and Parasuraman, 2011). The aim is to obtain authentic, innovative ideas and solutions of crowds that are believed to be of a professional calibre (Poetz and Schreier, 2012), though additional value from engaging in a crowdsourcing contest might be equally attractive (Piyathasanan et al., 2013) and independent from the quality of ideas generated. Value creation is considered an important manifestation of customer engagement behaviour (Kumar et al., 2010, Dong et al., 2008, Hollebeek, 2013, Hollebeek et al., 2016). Customer engagement and relationships researchers urge organisations to co-create value with their customers through a wider range of marketing activities (Venkatesan, 2017). In a crowdsourcing context, creative performance is the direct benefit of creative process engagement (CPE) (Bakker and Demerouti, 2008, Sapp, 1995, Mace and Ward, 2002), yet firms may also enjoy additional value from customer engagement
over time, a notion recently acknowledged in the customer engagement literature (Pansari and Kumar, 2017). Customers may for example contribute to a firm’s value by offering their knowledge (such as in creative crowdsourcing), but also through product purchases, other loyal behaviours and indirect ripple effects from customer engagement. Recent empirical evidence shows that customers’ CPE in a crowdsourcing task can create other types of value for both firms and participants, such as customer loyalty (firm value), and epistemic value (customer value) (Piyathasanan et al., 2013, Djelassi and Decoopman, 2013). Indeed, customer value creation is a likely outcome of customer engagement. Such value creation is important, as many large firms are encountering challenges in monitoring and appraising whether crowdsourced solutions lead to competitive, sustainable advantages (Jones et al., 2013). Firms would benefit from a clearer understanding of how CPE can facilitate value creation in the first place, and how to sustain it over time.

To explain the challenge, the paper turns to the (dis)confirmation of expectation paradigm commonly used in the customer satisfaction literature. Since “crowdsourcing initiatives hinge on individuals’ willingness to participate in these projects and their motivation to contribute valuable insight and ideas” (Füller et al., 2012, p. 137), they are typically organized as a competition or contest. A contest creates expectations for participants about the ranking of their submissions and associated monetary and non-monetary rewards. Only a few winning participants receive extrinsic recognition and rewards from the contest. The winners’ expectations are seemingly met, if not exceeded, resulting in perceived value from their participation and engagement in the crowdsourcing contest, and thus subsequent satisfaction with their engagement. However, most participants are likely to experience disappointment, leading to lower value perceptions and subsequent dissatisfaction.
Accordingly, this paper aims to examine:

1. the association between customer engagement in a crowdsourcing contest, and the resulting value creation for customers and/or the firm beyond the time of submission;

2. the extent to which customer perceived value and firm value shifts between the time of submission, and once participants learn of how well they fared in the crowdsourcing contest;

3. the extent to which participants’ disconfirmed expectations and their need for recognition moderate the association between customer engagement, and perceived firm and customer value following the announcement of the crowdsourcing results.

The study offers two specific contributions to the literature. First, it serves as an initial effort to investigate if and how the value created from customer engagement in crowdsourcing (operationalised as creative process engagement [CPE]) changes over time. Previous studies suggest that CPE creates value beyond the creative submission, but it is unclear how this value endures or changes over time (Piyathasanan et al., 2013, Djelassi and Decoopman, 2013). This study uses longitudinal data, collected at completion of the contest (Time 1) and announcement of winners and rankings (Time 2), and applies the lens of the honeymoon-hangover effect (Collins and Coltrane 1995), which indicates that perceptions of satisfaction (and associated value) may initially be inflated in a new relationship, but deteriorates over time.

The study also empirically examines under which conditions the CPE-value link varies, as a function of a participant’s disconfirmed expectations and need for recognition. In
other words, the study not only shows ‘what’ drives customer and firm value, but also ‘when’, i.e., under what conditions. The disconfirmation of expectations paradigm emphasises the pivotal role of expectations in the creation of customer satisfaction (Oliver, 1980). Beltramini and Evans (1988) found that employee’s expectations in a sales contest (i.e., “I expect to win”) were positively correlated with job satisfaction and performance; an effect that might be equally applicable in a crowdsourcing context, where participants invest time and effort and expect a good result. The need for recognition has previously been identified as an important driver of customer engagement and contribution in crowdsourcing (Djelassi and Decoopman, 2013, Brabham, 2008), because social appreciation and feedback from other people (e.g., peers and judges), or from an activity that they engage in, leads to positive subsequent behaviour (such as long-lived, highly-engaged participants) and value perceptions (Sawhney et al., 2005).

**Conceptual development**

We build on creativity theory, which establishes CPE as a central tenet (e.g., Gilson and Shalley, 2004, Zhang and Bartol, 2010a), and customer satisfaction research (Oliver, 1980, McKinney et al., 2002) to develop a model to explain value creation and continuance. The conceptual model is depicted in *Figure 1*. Value creation for the customer and the firm after the announcement of winners and rankings (Time 2) is a function of CPE at the time of submission (Time 1). Value creation from CPE beyond participation in the contest can be explained by disconfirmation of expectation and need for recognition. In the subsequent section, the study reviews existing literature in creativity and customer behaviour that is relevant to the main conceptual building blocks of the model.

- *Insert Figure 1 here* –
Creative (problem-solving) process engagement (CPE)

In a crowdsourcing contest (i.e., a creative advertising idea generation) that is considered complex and involves extended effort in creative problem-solving processes (Gilhooly et al., 2007), creativity is instrumental. Any type of engagement requires involvement and participation in a focal object (Brodie et al., 2011). Engagement in the creative process differs from ordinary involvement with a non-creative task, though it is comparable in that it refers to positive attachment to an activity consistent with the individual’s values (Zaichkowsky, 1985). As with other forms of customer engagement, the creative process entails stronger cognitive and affective commitment, by spending time and effort, to generate ideas or solutions over time (Mollen and Wilson, 2010, Gilson et al., 2005). Creative process engagement (CPE) is thus introduced as the main construct to capture participants’ engagement with the crowdsourcing contest until idea submission, and consists of three crucial aspects: problem identification, information search and idea generation (Reiter-Palmon and Illies, 2004, Zhang and Bartol, 2010a).

CPE and value creation

Customer engagement creates value (Dong et al., 2008, Brodie et al., 2011), an effect which also extends to CPE where value creation is either direct or indirect: besides the direct benefit of a usable creative solution, firms may enjoy additional effects from CPE beyond Time 1 (e.g., enhancing firm-customer relationships and social interactions), as may participating customers.

Firms often use online communities and social networks to host crowdsourcing contests, as these platforms fulfil the human needs for social interaction and facilitate a sense
of self-fulfilment (McInerney and Roberts, 2004). Understanding why and how individuals engage in specific media to satisfy their needs helps identify two customer value perceptions relevant to crowdsourcing: social value and epistemic value (Nambisan and Baron, 2009). CPE is therefore expected to result in social value (e.g., firm-customer relationship and reciprocity) and epistemic value (e.g., satisfy or arouse curiosity, and self-fulfilment) for participating customers (Jackson, 2002, Greaves and Farbus, 2006, Kozinets et al., 2008).

Social value arises where individuals perceive a sense of community and friendship through interaction with others (Reidpath et al., 2005), an effect well documented in studies on online collaborative communities (e.g., Chung and Buhalis, 2008). Collaborative crowdsourcing platforms enable participation and social interaction with others (Brabham, 2009) due to embedded socialising functions (e.g., websites, web-board, online communities and Facebook) (Leimeister et al., 2009, Schenk and Guittard, 2011). Accordingly, a higher degree of CPE in a crowdsourcing contest should enhance the participant’s perceived social value beyond Time 1:

**Hypothesis 1:** The higher the CPE at submission (Time 1), the more social value is created after receiving feedback (Time 2).

Epistemic value, or self-fulfilment, is created if an individual is satisfied with his/her aroused curiosity, fulfilled knowledge, and/or improved skills (Sheth et al., 1991). Epistemic value is an important outcome for various crowdsourcing types, such as Wikipedia and crowdfunding (Fallis, 2008), because the challenge of tackling creative problems arouses curiosity. Participants may then satisfy their curiosity by engaging in the creative process to solve these problems; CPE should thus enhance epistemic value perceptions (Hars and Ou, 2002).
Hypothesis 2: The higher the CPE at submission (Time 1), the more epistemic value is created after receiving feedback (Time 2).

Customer value perceptions are a key predictor of subsequent behaviours such as loyalty, satisfaction, intention to recommend and re-purchase (Fornell et al., 1996, Sirdeshmukh et al., 2002, Cronin et al., 2000). For example, customers stay loyal to a firm if they perceive greater value than they expect to obtain from competitors (Bitner and Hubbert, 1994). Similarly, McDougall and Levesque (2000) suggest that perceived value leads to less brand switching and greater customer loyalty.

For firms hosting crowdsourcing contests, knowledge-sharing intentions and customer loyalty are critical outcomes of customer value perceptions, above and beyond the quality of the creative submissions. Knowledge-sharing intention is the willingness to collaborate and contribute relevant knowledge and ideas to the firm (Desouza and Awazu, 2005), for example by participating in future crowdsourcing contests. The customer engagement literature also establishes how customers' voluntary contributions, such as offering their knowledge, skill and creativity, create firm value (Harmeling et al., 2017, Hollebeek et al., 2014). Customer loyalty captures the intention to continue a good relationship with a firm, through positive word-of-mouth and repurchasing (Dick and Basu, 1994). The link between social and epistemic value perceptions, behavioural intentions and customer loyalty is well established in online marketing research (see e.g., Cheng et al., 2009, Gruen et al., 2006). Bitner et al. (2008) argue that service firms can achieve loyalty through memorable and meaningful experiences, as simply providing a superior core service no longer guarantees loyalty. Creative crowdsourcing and resultant customer value may constitute such an experience. We thus posit that social and epistemic value, as components of consumers’ overall perceived value from crowdsourcing
after receiving feedback (Time 2), would equally lead to knowledge-sharing intention and customer loyalty in a crowdsourcing context.

**Hypothesis 3:** Social value perception is positively related to (a) knowledge-sharing intention and (b) customer loyalty.

**Hypothesis 4:** Epistemic value perception is positively related to (a) knowledge-sharing intention and (b) customer loyalty.

**Honeymoon-hangover effect and a change in value creation over time.**

To explain how value created in a crowdsourcing contest may change over time, we tap into a phenomenon known as the ‘honeymoon-hangover effect’ in social psychology. The *honeymoon effect* is “a positive initial effect on satisfaction or performance attributed to conditions that are most favourable at the early stages of a new relationship or venture, in comparison to conditions encountered as the relationship or venture continues” (Dacko, 2007, p.255). Just like in marital satisfaction during the honeymoon period (Easterlin, 2003), novelty, anticipation, excitement, harmony, or similar positive factors, may be at play (Collins and Coltrane, 1995, Dacko, 2007).

However, the honeymoon effect is temporary because satisfaction with collaborative relationships may change over time, often due to unfavourable situational factors or events such as unexpected feedback, unfulfilled expectations or misunderstanding (McEvoy et al., 2005, Dacko, 2007). The announcement of contest winners and feedback to all participants is a discrete unexpected event. The resulting *honeymoon-hangover effect* has been observed in various areas, such as the attendance rate and use of new sport facilities, the
adoption of information technology, and new employment in an organization (Fichman and Kemerer, 2012, Boswell et al., 2005, McEvoy et al., 2005). For example, early in the IT development cycle, innovative technologies typically enjoy a honeymoon effect as there is widespread adoption from an immature market, then the rate of adoption drops over time (Fichman and Kemerer, 2012).

We examine the value creation from CPE in a crowdsourcing contest through the honeymoon-hangover effect, because customers’ value perceptions at the time of submitting their solution (Time 1) might change once they receive the contest results, such as rewards, ranking and feedback from peers and judges about their creative performance (Time 2). That is, while initial value perceptions tend to be particularly positive, we predict a decline over time. Except for the few winners of the contest, participants may be disappointed with the unexpected feedback and unmet expectation, resulting in a decrease of value perceptions from Time 1 to Time 2.

*Hypothesis 5: When participants receive feedback (Time 2), their perceptions of (a) social value; and (b) epistemic value will be lower than at Time 1.*

*Hypothesis 5: When participants receive feedback (Time 2), firm’s value from (c) knowledge-sharing intention; and (d) customer loyalty, will be lower than at Time 1.*

Disconfirmation of expectation paradigm

In how far the CPE-value link is subject to a honeymoon-hangover effect obviously depends on the presence and valence of unexpected feedback, i.e. the (positive or negative) disconfirmation of participants’ expectations. Based on the disconfirmation of expectation paradigm, customer satisfaction depends on the consistency between an individual’s initial
performance expectations and perceived performance (e.g., Oliver, 1980, Patterson, 1993). Customers are satisfied when they experience positive disconfirmation, i.e. when perceived performance exceeds prior expectations, and conversely dissatisfied when experiencing negative disconfirmation (e.g., Oliver, 1980, Patterson et al., 1996). Note that customers may be satisfied with poor performance if prior expectations are relative low. For example, participants who receive a low ranking from a crowdsourcing contest may in fact be satisfied with the feedback because they did not expect much. We thus argue that the association between CPE and social and epistemic value is stronger when a participant’s expectation about their ranking and rewards from the contest are exceeded. Such an interaction effect would also predict a weaker link when a participant’s creative performance ranking is lower than they initially expected.

**Hypothesis 6:** The impact of CPE at Time 1 on (a) social value and (b) epistemic value at Time 2 will be stronger under conditions of a positive (rather than negative) disconfirmation of expectation.

**Need for recognition**

The positive effect of CPE on value creation may further increase for participants with a high need for recognition. This stable personality trait relates to “the need to have one’s self, one’s works, and other things associated with one’s self, known and approved by others” (Schaffer, 1953, p. 1). Member of any community tend to satisfy their need for recognition by seeking feedback, praise, acceptance, respect, or attention from other members such as peers, supervisors and judges (Busch et al., 2008). Whenever recognised and praised for an accomplishment by others, an individuals’ satisfaction and enthusiasm to perform better on the task or to have more social contact will increase (Hill, 1987, Brabham, 2008). The positive effect of CPE on value creation is thus likely to be stronger for participants with
a high need for recognition. Receiving feedback or rewards can reinforce an individuals’ perception as a valued contributor to the task (Taylor et al., 1984). For example, in their investigation of innovation creation by online basketball communities, Fuller et al. (2007) reported that designers, who are driven by the need for recognition and feedback from a knowledgeable audience, contributed significant time and effort to designing basketball shoes, and sharing their work with the online community. In turn, the designers expected to further improve and fulfil their knowledge and skills from their contributions. Nambisan and Baron’s (2009) study of customer participation and value co-creation activities found that need for recognition may moderate the impact of interactions in a virtual customer environment (e.g., online discussion forums) on future participation behaviour. Accordingly, based on earlier discussion, it is proposed that:

\[ \text{Hypothesis 7: The impact of CPE at Time 1 on (a) social value and (b) epistemic value at Time 2 will be stronger under conditions of a higher (rather than lower) need for recognition.} \]

**Methodology**

**Research setting and participants**

Data was collected from participants in a creative crowdsourcing contest, conducted by a leading national restaurant chain in Thailand with over 350 restaurants, annual sales exceeding US$200 million, and annual marketing spend of about US$ 8 million. The contest called for ‘new creative advertising ideas’ that may be used for the firm’s marketing communication campaign in the following year; it was announced via the firm’s official Facebook page, which had more than 100,000 followers.
Potential contributors could register to participate in the crowdsourcing task via the firm’s official microsite, which linked into the firm’s website and Facebook. The microsite was used for registration, discussion, submission of creative ideas, and data collection. The contest duration was 75 days. 250 participants submitted a total of 212 advertising ideas either individually or as a part of a team. First- and second-place winners received a MacBook Pro and iPad, respectively. Entries ranked third to tenth received a gift voucher worth $100 and a certificate. All submitted ideas were rated by three subject-matter experts in the field of advertising and marketing communication.

Online questionnaires were used in both Time 1 (i.e., upon submitting their advertising ideas but before receiving any feedback) and Time 2 (i.e., after participants received feedback in the form of ranking and/or rewards). The questionnaires were pre-tested with 30 respondents, prior to the launch of the crowdsourcing contest, only requiring minor revisions to improve overall understanding and content. When crowdsourcing participants (N=250) submitted their advertising ideas (see examples of submitted ideas in Appendix D), they were asked to participate in the study, and received a link to the Time 1 online questionnaire. To minimise response bias, respondents were clearly informed that their personal information was confidential and secure, and their responses would not affect their contest results (Nestor and Schutt, 2011). Respondents were not forewarned about the Time 2 data collection, to minimize bias in responding to the second questionnaire (Churchill and Iacobucci, 2009). Total valid responses at Time 1 were 219 (87.6% response rate). One month after the closing date for idea submission, each participant received the ranking of their submission from the judges, and any rewards. They were then immediately contacted by telephone and email to seek cooperation and received a link to the Time 2 online questionnaire. Two telephone follow-ups were undertaken after one and two weeks if no
response was received, leading to a total of 154 valid responses (70% of respondents from Time 1). For each data collection, respondents received a $5 incentive.

**Measurement development**

*In both Time 1 and Time 2,* the study used the same measurement to capture value perception, including social value, epistemic value, knowledge-sharing intention and customer loyalty. Scales were adapted from prior relevant studies that exhibited strong construct reliability and validity, with minor wording modifications to fit the research context. All measures, except disconfirmation of expectation, used a seven-point Likert scale, ranging from “strongly disagree” to “strongly agree.” Social and epistemic value were each captured with four items from Mathwick et al. (2008) and Sheth et al. (1991). Knowledge-sharing intention was measured by three items adapted from Kumar et al. (2010), and seven indicators measuring customer loyalty were drawn from Zeithaml et al. (1996). Cronbach’s alphas and composite reliability for all constructs exceeded 0.70.

At *Time 1,* we also measured CPE with 11 items from Zhang and Bartol (2010), to capture the three dimensions of problem identification, information searching, and idea generation, and need for recognition with five items based on Hars and Ou (2002) and Wasko and Faraj (2005). Demographic data (gender, age, education) were also collected, and we asked questions related to the crowdsourcing task in this study (for example, time spent on the task and perception of task complexity) and patronage behaviour (frequency, recency).

At *Time 2,* all value perceptions were measured again with the same scales as in Time 1. In addition, disconfirmation of expectations was measured as the perceived gap between expectation and performance (McKinney et al., 2002), on a five point “Much worse than expected” to “Much better than expected” scale (Oliver, 1980).
Control variables

We included individual/team submission and prior relevant creative experience as control variables, operationalized as dichotomous variables and measured at Time 1, though little evidence supports the view that they influence customers’ perceived value in crowdsourcing. Inclusion of these control variables is designed to provide a more robust test of the hypotheses.

Analysis and Results

Data analysis

Partial Least Square (PLS) path modelling was used to estimate both main and interaction effects. PLS path modelling method was most suited to our research because it is more robust when a study has a relatively small sample size (Green and Ryans, 1990); when a multivariate normal distribution cannot be assured and variables are highly skewed (Cassel et al., 1999); and to estimate a complex model including second-order constructs with many latent and manifest indicators (Venaik et al., 2005). To examine potential changes in value perceptions at Time 1 and Time 2, paired-sample T-tests were used to examine differences between the means for the two sets of scores from the same group of participants (Coakes and Steed, 2007).

Half of the respondents (53.2%) were female, and most (89.0%) held at least a bachelor’s degree. The average age was 26.7 years (SD = 9.8 years), and average patronage was 8.5 years (SD = 5.1 years). Respondents visited a branch of the restaurant chain on average 1.87 times a month. Almost half of them (46.8%) had relevant previous creative experience, and about one quarter (26.0%) participated in this crowdsourcing task as a team of two or three.
Measurement Model: Validity and reliability

Internal reliability was established, as composite reliability (see Table 1) for all multi-item constructs ranged from .88 to .94 and thus exceeded the recommended threshold value of .70 (Hair et al., 2011). The average variance extracted (AVE) was used to establish adequate convergent and discriminant validity (Fornell and Larcker, 1981). As seen in Table 1, the AVEs for all multi-item constructs range from .51 to .85, and thus meet the proposed .50 rule-of-thumb (Bagozzi and Yi, 1988). The square root of each AVE (presented on the diagonal in Table 2) is higher than the inter-correlations of the focal construct and any other construct (presented off the diagonal) in the model, suggesting adequate discriminant and convergent validity.

- Insert Table 1 here -

As reported in Table 1, the R-squares of each inner latent construct ranged from .16 to .29, indicating weak to moderate values (Chin, 1998). Further, the global criterion for goodness-of-fit (GoF) describes the structural model’s quality. Tenenhaus et al. (2005) suggested that the GoF \( 0 \leq GoF \leq 1 \) can be assessed by “the geometric mean of the average communality and the average R-squares (for endogenous constructs):

\[ GoF = \sqrt{communality \times R^2}. \]

The GOF value of .40 indicates large effect sizes (Wetzels et al., 2009).

- Insert Table 2 here -

A PLS analysis was also conducted to determine whether interaction was present between the hypothesized moderator variables and the predictor variable. Correlation
between the two moderators (i.e., disconfirmation of expectation and need for recognition) were also checked. The findings reveal that while disconfirmation of expectation is a pure moderator variable, need for recognition is a quasi-moderator variable because it has a moderate correlation with CPE ($r = 0.56$). Further, we also examined multi-collinearity issues of the structural model by assessing a set of predictors of knowledge-sharing intention and customer loyalty. The tolerance values and VIF values were above .20 and below the 5 threshold respectively, i.e. multi-collinearity among the predictor constructs is not present (Hair, 2011).

Next, we examined the $q^2$ value, obtained by using the blindfolding procedure in SmartPLS. As seen in Table 1, all $q^2$ value of all endogenous latent constructs were larger than zero, indicating the model’s predictive relevance (Hair et al., 2011). Further, the PLS-SEM model’s results were evaluated and assessed. The $f^2$ effect size indicated a level of construct relevance in explaining selected endogenous latent constructs. Results of 0.02, 0.15, and 0.35 were indicated - a small, medium, and large $f^2$ and $q^2$ effect size respectively (Hair et al., 2014). As seen in Table 3, social and epistemic value has a small $f^2$ effect size in explaining $R^2$ value of knowledge-sharing intention. Additionally, while epistemic value has a small $f^2$ effect size in explaining $R^2$ value of customer loyalty, social value has a medium $f^2$ effect size.

- Insert Table 3 here -

Results

We conducted a paired-samples t-test to examine the extent to which consumer perceived value and firm value shifts across two time periods (Time 1 and Time 2). As seen in Table 4, all mean values of customer perceived value in Time 1 were higher than those in Time 2. The findings indicated that, after completion of a crowdsourcing contest, once
participants were made aware of how well they fared in the contest, and whether or not they received an extrinsic reward, their social value perceptions, knowledge-sharing intention and customer loyalty decreased (p< .05). However, their epistemic value perception did not change over time. Hence, H5a, H5c, and H5d are supported, whereas H5b is rejected.

- Insert Table 4 here -

The structural model estimation results (Figure 2) show that all hypothesised relationships were statistically significant (Table 5). The findings revealed that CPE drives customers’ perceptions of social value (H1: β = .195 [p<.05]; R² = 24.5%) and epistemic value (H2: β = .213 [p<.05]; R² = 29.3%). The results also suggested that knowledge-sharing intention can be explained by social value (H3a: β = .245 [p<.01]) and epistemic value (H4a: β = .220 [p<.05]), as can customer loyalty (R² = 26.8%; H3b: β = .385 [p<.001]; H4b: β = .215 [p<.05]).

- Insert Figure 2 here -

With regard to the moderating hypotheses, we calculated interaction terms by multiplying the mean-centred indicators CPE as the predictor and each moderator (i.e., disconfirmation of expectation and need for recognition) (Chin et al., 2003). The beta values of all moderator path coefficients were statistically significant. Both disconfirmation of expectation and need for recognition exhibited positive moderating effects on social value (H6a: β = .205 [p<.01]; H7a: β = .365 [p<.001]) and epistemic value (H6b: β = .363 [p<.001]; H7b: β = .333 [p<.01]). Finally, the individual/team submission and prior creative experience control variables were not significant.
Discussion and implications

Key findings

The empirical evidence summarised in Table 5 presented a number of interesting findings. Firstly, CPE indeed drives customers’ social and epistemic value. This customer value also converts into positive customer behaviours that create value for the crowdsourcing host firm, namely knowledge-sharing intentions and loyalty. Extending on previous research, firms thus receive extra value from investing resources in a crowdsourcing contest, in addition to the quality of creative submissions. Value creation emerges both at the submission stage and the announcement of winners. These findings contribute to current social networking research, by illustrating a continuum of value creation over time from customer engagement.

- Insert Table 5 here -

However, all value decreased over time, except epistemic value, a phenomenon which can be explained by the honeymoon–hangover effect. When submitting a creative solution to a crowdsourcing contest (i.e., Time 1), it is likely that participants perceive inflated satisfaction and accompanying sense of value creation, facilitated by the excitement of new relationships with the firm and other contest participants (Collins and Coltrane, 1995). During this time, participants may see engagement in the creative process as a means to socialise with others, reach self-fulfilment and satisfy their aroused curiosity. That is, initial value perceptions at the time of submission tend to be particularly positive.

However, after the announcement of winners, when each participant receives feedback (i.e., Time 2), customers’ expectations play an important role in determining
subsequent perceived value. Participants who received an unexpectedly disappointing ranking below their expectations perceive less social value, which also reduces their intention to share knowledge with firms in future contests, as well as their brand loyalty. Interestingly, this dissatisfaction does not affect epistemic value perception. It seems that epistemic value tends to be stable, and it transfers across to Time 2. The empirical results show that need for recognition and positive disconfirmation of expectation indeed strengthen the impact of CPE on customer social and epistemic value perceptions beyond the submission stage.

Theoretical implications

Existing research in customer engagement and value creation (Venkatesan, 2017, Harmeling et al., 2017, Hollebeek et al., 2014) highlights the need to understand and evaluate customer engagement and its contribution to a firm’s marketing activities. Our longitudinal study answers this call and empirically examines the effect of engagement with a specific marketing activity – a creative crowdsourcing contest - on perceived value for customer and firm. Overall, our study makes three important contributions to the growing research stream on consumer co-creation and user innovation. First, crowdsourcing researchers have focused on examining an association between motivation (intrinsic and extrinsic) and quality of ideas (as crowdsourcing outcome) in order to understand how customers engage in crowdsourcing and how they create value (e.g., Kaufmann et al., 2011, Leimeister et al., 2009). However, since the quality of crowdsourcing ideas is often disappointing, it is important to know whether engagement in crowdsourcing creates value to participants and firms regardless. With the exception of few studies measuring customer value (e.g., Djelassi and Decoopman, 2013), previous research has mostly speculated about the emergence and transition of value creation from customer engagement in crowdsourcing. The longitudinal design of our study
showed that value is indeed created, and continues beyond idea submission, laying the
foundation for future research.

Second, the findings provide empirical support for the honeymoon-hangover effect
(Collins and Coltrane, 1995) in crowdsourcing, in that perceived customer and firm value
decline over time. That is, firms enjoyed the honeymoon effect (customers perceived an initial
higher value from the task) for a short period of time. Once participants received feedback from
the contest (in our study, about a month after the closing date for idea submission), the
hangover effect was activated (i.e., customers perceived less value).

Third, the need for recognition and disconfirmation of expectations moderate the
link between CPE and value creation. While prior research has only focused on ‘what’ drives
value creation, this study enhances the existing crowdsourcing literature by breaking ground
in understanding ‘when’ (i.e., under what condition) customer and firm value occurs. Our
study supports Nambisan and Baron’s (2009) call for considering customer psychological
variables that may moderate the impact of customer interaction in value co-creation activities
on customer behaviors. Further, there is consistent empirical support for the disconfirmation
of expectations in various contexts, and the present study also supports the proposition that
initial expectations and perceived performance (i.e., feedback and rewards from judges)
interact to explain customer value creation in a crowdsourcing context.

Managerial implications

There are two core managerial contributions from this study, as summarised in Table
6. First, given the declining value once the contest results are released, managers should
focus on converting customers’ value from participating in the crowdsourcing contest into
firm value in the weeks between submission and announcement of winners. Doorn et al.
(2010) suggest several avenues to further stimulate engagement, such as through customer communities and special rewards that might be equally beneficial to sustain the creation of firm value in crowdsourcing. Indeed, online brand communities can create strong customer engagement (Brodie et al., 2013).

- Insert Table 6 here -

Second, crowdsourcing contests can be designed to take advantage of the role that need for recognition and the disconfirmation of expectation play in the CPE-value creation link. Feedback plays a central role, because engagement in crowdsourcing “can […] give rise to feelings of being exploited and/or cheated if the crowdsourcing practices are perceived as excessive, not credible or unfair” (Djelassi and Decoopman, 2013, p.688). Recognition in terms of appraisal, social recognition, rewards and feedback from others results in positive subsequent behaviour (Jawahar, 2006), and it can be a catalyst for satisfying the need for recognition of participants. This could be in the form of clear, performance-based feedback from judges, or a multi-source feedback system that collects performance evaluation from more than one source (e.g., using crowd voting, which allows online customers and participants to vote for their favourite submitted ideas). Multi-source feedback can satisfy the need for recognition, as well as fulfil participants’ self-improvement (i.e., epistemic value perception) because (a) it helps participants better understand how they are viewed by others, and (b) it suggests areas for development and performance improvement (London and Smither, 1995).

To benefit from the value-boosting effect of positive disconfirmation, the contest should be set up in a way that maximizes positive disconfirmation, and avoids negative disconfirmation, by lowering participants’ expectations. For example, after participants
submit their creative ideas, firms could emphasize the prestigious and competitive nature of the contest, and the large volume of submitted ideas. Only a few winners receive positive feedback and rewards, though recognition and rewards are crucial for driving engagement and satisfaction. Hence, firms may employ a combination of rewards (intrinsic and extrinsic) for a crowdsourcing contest, to motivate and satisfy participants’ expectations, resulting in satisfaction (Chou, 2013). Types of rewards could include ‘fixed action rewards’ (participants will receive when they complete a certain task), ‘random rewards’ (each participant has the chance to receive a gift from the contest), and ‘top 100-submitted-ideas rewards’.

Limitations and Concluding Remarks

While this research offers insights into the drivers of value creation and its changes over time, it is not without limitations. The first limitation is the nature of the study context, where a firm outsourced a complex task to crowds. Hence generalization of the results to other contexts might be limited to complex, rather than to easy tasks, where participants solve a generic routine task, such as a short text translation, with relatively low CPE.

Second, the scope of the study was limited to one product (fast-food), though future research could look at other product or service types. Third, given the scope of the study, there are several other customer-related variables which may further explain the nature of value creation from crowdsourcing. Potential moderator variables to be explored in future research are social identity and perceived organizational support.

Whereas we collected data from participants at two different times, future research may investigate changes in value creation in more than a single time lag, or may examine the transition of value creation across more than one crowdsourcing project hosted by a firm. Similarly, other drivers unrelated to the crowdsourcing contest might account for changes in
value between Time 1 and Time 2, such as an unpleasant customer experience when visiting
the restaurant, negative word of mouth or general publicity, or unwelcome firm activities
such as price or product changes. Last, if marketers can understand the duration of the
honeymoon-hangover effect on value creation in a crowdsourcing context, firms can know
when to intervene and put in place effective avoidance strategies (e.g., launching a new
activity, providing personal feedback, or motivating with tangible or intangible rewards).
However, duration was not considered here, though points out a promising direction for future
research to investigate the duration of the honeymoon-hangover effect in a crowdsourcing
context.

In summary, our study makes three main contributions. First, we show that customer
engagement drives customer and firm value following the announcement of crowdsourcing
results, beyond the creative submission. Second, we established that except for epistemic
value, all crowdsourcing value suffers to some extent from a honeymoon-hangover effect.
Once participants were aware of their performance, social value perception, knowledge-
sharing intention and customer loyalty decreased over time.

Last, the relationship between customer engagement and firm and customer value is
contingent on disconfirmation of expectations, and the need for recognition. When a
participant’s expectation about their ranking and rewards from the contest are exceeded,
and/or when a participant’s need for recognition is high, the links between CPE and customer
value are strengthened. The findings should inspire future researchers to better understand the
nature of value creation in various crowdsourcing contexts.

Appendix B: Contest Details

"[The firm] would like to invite you submit creative advertising idea(s) under a theme of “Happiness with [the firm]”. In order to present your idea, you can submit your ideas in several formats such as a description, a story, a picture, a video clip, or a sound clip. We will score your idea(s) base on novelty and usefulness."

Examples of ideas submissions via the Firms’ microsite that was embedded in their Facebook Fanpage. Participants can submit idea(s) (e.g., advertising storyboard and storyline), share them with friends, and vote for their favorite creative advertising ideas.
