## Abstract

According to personality psychology, personality traits determine many aspects of human behaviour. However, validating this insight in large groups has been challenging so far, due to the scarcity of multi-channel data. Here, we focus on the relationship between mobility and social behaviour by analysing two high-resolution longitudinal datasets collecting trajectories and mobile phone interactions of  $\sim 1000$  individuals. We show that there is a connection between the way in which individuals explore new resources and exploit known assets in the social and spatial spheres. We point out that different individuals balance the exploration-exploitation trade-off in different ways and we explain part of the variability in the data by the big five personality traits. We find that, in both realms, extraversion correlates with an individual's attitude towards exploration and routine diversity, while neuroticism and openness account for the tendency to evolve routine over long time-scales. We find no evidence for the existence of classes of individuals across the spatio-social domains. Our results bridge the fields of human geography, sociology and personality psychology and can help improve current models of mobility and tie formation.

## Introduction

Two forces shape our social and spatial behaviour. On the one hand, we all experience limitations [1]. Time, cognition, age, the need for food, etc. all constrain our behaviour. On the other hand, each one of us is characterised by personality traits that make us, if perhaps not unique, at least different from many. Personality psychology conjectured a long ago that a set of personality traits underlie all aspects of human behaviour [2, 3].

In the social realm, individuals cope with cognitive and temporal constraints by establishing and maintaining connections in a distinctive [4, 5] and persistent [4] manner. For example, the size of an individual's social circle is bounded under  $\sim 150$ , the so-called Dunbar number [6], but varies among individuals around this limit [7]. These differences result from an interplay between physical and extrinsic factors such as gender [8], age [9] and socio-economic status [10] as well as from stable individual dispositions underlying personality [11].

Spatially, individuals are characterised by an *activity space* of repeatedly visited locations within which they move during their daily activities [12], but this geo-spatial signature varies in size [13] and spatial shape [14]. However, unlike the social case, the conjecture that individuals' spatial behaviour is persistent in time [15] had not been verified until recently.

Here, we capitalise on the recent discovery that the size of the activity space is conserved and correlates with the social circle size [16] to test the conjecture that the same personality dispositions in part determine social and spatial behaviour. We test this theory by analysing two long-term datasets consisting of  $\sim 1000$  individuals mobility trajectories and their phone interactions (for previous studies see section '*State of the art*' below).

First, we test the hypothesis that the strategies individuals adopt in order to choose where to go and with whom to interact are similar. Then, we identify and characterise the prevailing socio-spatial

profiles appearing in the datasets. Finally, we show that socio-spatial profiles can be partially explained by the widely adopted big-five personality trait model, often used to describe aspects of the social and emotional life [7,11,17–22]. In the section ‘*State of the art*’, we review the relevant literature; in ‘*Methods*’ we describe data collection and pre-processing, and we provide details of the methods implemented; in ‘*Results*’ we present our findings.

## State of the art

Individual-level variability in social and spatial behaviour has mostly been investigated in isolation so far, with few notable efforts to reconcile the two. Here, we briefly review the empirical findings in the two domains.

### The social domain

Individuals deal with limited time and cognitive capacity resulting in finite social networks [6, 23] by distributing time unevenly across their social circle [4, 24–28]. While this is a shared strategy, there is clear evidence for individual-level variation. First, social circles vary in terms of diversity: they differ in size [7] - within a maximum upper-bound of  $\sim 150$  individuals [6] - and in structure [4, 29]. Second, individuals display different attitudes towards exploration of social opportunities as they are more or less keen on creating new connections [30–33]. Finally, individuals manage social interactions over time in different ways. Some are characterised by high level of stability as they maintain a very stable social circle, while others renew their social ties at high pace [5].

These heterogeneities can be partially explained by factors including gender [8, 34], age [9, 35, 36], socio-economic status [10, 37] and physical attractiveness [38]. Moreover, as conjectured by personality psychologists [2, 39], differences in personalities partially explain the variability in social circle composition [7, 11, 17, 40–44], and the different attitudes towards forming [30, 45], developing [20, 46] and replacing [29] social connections. It is worth noticing that many of these findings are recent, resulting from the analysis of digital communication traces.

### The spatial domain

Constraints including physical capabilities, the distribution of resources, and the need to coordinate with others limit our possibilities to move in space [1]. Individuals cope with these limitations by allocating their time within an activity space of repeatedly visited locations [47], whose size is conserved over several years according to a recent study based on high-resolution trajectories [16], and previous ones based on unevenly sampled and low spatial resolution data [48, 49]. The activity space varies across individuals in terms of size [16] and shape [14]: it was shown that two distinct classes of individuals can be identified based on the spatial distribution of their locations, similarly to the social domain [5]. Heterogeneities in spatial behaviour can be explained in terms of gender [50], age [51, 52], socio-economic [35, 53] and ethnic [54] differences. There has only been sporadic efforts to include personality measures in geographic research, despite the strong connections between the two [55]. Recent works [44, 56] suggest that spatial behaviour can be partially explained from personality traits. However, in [56], this understanding is based on biased data collected from location-based social networks. In [44], the connection between spatial behaviour and personality is not investigated extensively, as it is not the main focus of the study.

### Social and spatial connection

Recently, connections between the social and spatial behaviour of pairs [57–62] and groups [63] of individuals have been demonstrated, and used to design predictive models of mobility [58, 64, 65] or social ties [59, 66–68]. Shifting the attention to the individual level, recent works based on online social network data [69, 70], mobile phone calls data [62] and evenly sampled high resolution mobility trajectories [16] have shown correlations between the activity space size and the ego network structure, calling for further research to more closely examine the connections between social and spatial behaviour at the individual level.

## Methods

### Data description and pre-processing

Our study is based on 850 high resolution trajectories and call records of participants in a 24 months longitudinal experiment, the Copenhagen Networks Study (CNS) [71]. Results on the connections between social and spatial behaviour were corroborated with data from another experiment with fixed rate temporal sampling, but lower spatial resolution and sample size: the Lausanne Data Collection Campaign (MDC) [72, 73], lasted for 19 months (see Table 1).

	$N$	$\delta t$	$T$	$\delta x$	$TC$
CNS	850	16 s	24 months	10 m	0.84
MDC	185	60 s	19 months	100-200 m	0.73

Table 1: **Characteristics of the mobility datasets considered.**  $N$  is the number of individuals,  $\delta t$  the temporal resolution,  $T$  the duration of data collection,  $\delta x$  the spatial resolution,  $TC$  the median weekly time coverage, defined as the fraction of time an individual’s location is known.

#### CNS dataset

The Copenhagen Networks Study (CNS) experiment took place between September 2013 and September 2015 [71] and involved  $\sim 1000$  Technical University of Denmark students ( $\sim 22\%$  female,  $\sim 78\%$  male) typically aged between 19 and 21 years old. Participants’ position over time was estimated combining their smart-phones WiFi and GPS data using the method described in [16, 74]. The location estimation error is below 50 meters in 95% of the cases. Participants’ calls and sms activity was also collected as part of the experiment. Individuals’ background information were obtained through a 310 questions survey including the Big Five Inventory [75], which measures how individuals score on five broad domains of human personality traits: openness, conscientiousness, extraversion, agreeableness, neuroticism. Data collection was approved by the Danish Data Protection Agency. All participants provided individual informed consent. Mobility patterns of participants in the CNS experiment display statistical properties consistent with previous literature [13], as shown in [16].

#### MDC dataset

Data was collected by the Lausanne Data Collection Campaign between October 2009 and March 2011. The campaign involved an heterogeneous sample of  $\sim 185$  volunteers with mixed backgrounds from the Lake Geneva region (Switzerland), who were allocated smart-phones [73]. In this work we used GSM data, that has the highest temporal sampling. Following Nokia’s privacy policy, individuals participating in the study provided informed consent [73]. The Lausanne Mobile Data Challenge experiment involves 62% male and 38% female participants, where the age range 22-33 year-old accounts for roughly 2/3 of the population [76].

### Metrics

In this section, we define the concepts and metrics used to quantify the social and spatial behaviour of an individual  $i$ .

**Exploration behaviour** is characterised by the following quantities:

*Number of new locations/week:*  $n_{loc}(i, t)$  is the number of locations discovered by  $i$  in the week preceding  $t$ . We discard data collected in the first 20 weeks.

*Number of new ties/week:*  $n_{tie}(i, t)$  is the number of individuals who had contact with  $i$  (by sms or call) for the first time in the week preceding  $t$ .

**Exploitation behaviour** can be quantified by considering:

*Activity space:* The set  $AS(i, t) = \{\ell_1, \ell_2, \dots, \ell_j, \dots, \ell_C\}$  of locations  $\ell_j$  that individual  $i$  visited at least twice and where she spent a time  $\tau_j$  larger than 200min during a time-window of  $T = 20$  weeks preceding time  $t$  (see Supplementary Material for the analysis with  $T = 30$  weeks). Among the locations in the activity space,  $i$  visited  $\ell_j$  with probability  $p(\ell_j) = \tau_j / \sum \tau_j$ . (It is worth noting that this time-based definition of activity space includes all significant locations independently of their spatial position and it is only loosely connected with space-oriented definitions widespread in the geography literature such as the “standard deviational ellipse” and the “road network buffer” [77]).

*Social circle:* The set  $SC(i, t) = \{u_1, u_2, \dots, u_j, \dots, u_k\}$  of individuals  $u_j$  with whom individual  $i$  had a number of contacts  $n_j > 5$  by sms or call during a time-window of  $T = 20$  consecutive weeks preceding time  $t$  (see Supplementary Material for the analysis with  $T = 30$  weeks). The probability that  $i$  has contact with a given member  $u_j$  of her social circle is  $p(u_j) = n_j / \sum n_j$ .

For these two sets  $AS(i, t)$  and  $SC(i, t)$ , we consider their sizes  $C(i, t)$  and  $k(i, t)$ , quantifying the number of favoured locations and social ties, respectively; their entropies  $H_{AS}(i, t)$  and  $H_{SC}(i, t)$ , measuring how time is allocated among locations and ties; their stabilities  $J_{AS}(i, t)$  and  $J_{SC}(i, t)$ , quantifying the fraction of conserved locations and ties, respectively, across consecutive non-overlapping windows of  $T = 20$  weeks (see Supplementary Material for  $T = 30$ ); their rank turnovers  $R_{AS}(i, t)$  and  $R_{SC}(i, t)$  measuring the average absolute change in rank of an element in the set between consecutive windows. The mathematical definition of these quantities is provided in Table 2

	Activity space	Social circle
1) Size	$C(i, t) =  AS_i(t) $	$k(i, t) =  SC(i, t) $
2) Entropy	$H_{AS}(i, t) = \sum_{j=1}^{C(i, t)} p(j) \log p(j)$	$H_{SC}(i, t) = \sum_{j=1}^{k(i, t)} p(j) \log p(j)$
3) Stability	$J_{SC}(i, t) = \frac{ SC(i, t) \cap SC(i, t - T) ^*}{ SC(i, t) \cup SC(i, t - T) }$	$J_{AS}(i, t) = \frac{ AS(i, t) \cap AS(i, t - T) ^*}{ AS(i, t) \cup AS(i, t - T) }$
4) Rank Turnover	$R_{AS}(i, t) = \sum_{j=1}^N \frac{ r(j, t) - r(j, t - T) ^{**}}{N}$	$R_{SC}(i, t) = \sum_{j=1}^N \frac{ r(j, t) - r(j, t - T) ^{**}}{N}$

---

\* Here  $T = 20$  weeks, see Supplementary Material for the analysis with  $T = 30$  weeks

\*\*  $r(\ell_k, t)$  and  $r(u_k, t)$  denote the rank of a location  $\ell_k$  and individual  $u_k$  at  $t$ , respectively

---

Table 2: **Definition of the metrics characterising the activity space and the social circle.** 1) The size of a set is the number of elements in the set 2) We compute the entropy of a set considering the probability  $p(j)$  associated to each element  $j$  of the set. 3) We measure the stability  $J_{AS}$  by computing the Jaccard similarity between the activity space at  $t$  and at  $t - T$ , with  $T = 20$  weeks.  $J_{SC}$  is computed in the same way for the social circle. 4) We compute the rank turnover of a set by measuring for each of its elements  $j$  the absolute change in rank between two consecutive time windows of length  $T = 20$  weeks. The rank is attributed based on the probability  $p(j)$ . The average absolute change in rank across all elements corresponds to the rank turnover.

### Other metrics

In order to compare the difference in entropy between two different sets, we compute their Jensen-Shannon divergence (JSD). The JSD between two sets  $P_1$  and  $P_2$  is computed as  $JSD(P_1, P_2) = H(\frac{1}{2}(P_1 + P_2)) - \frac{1}{2}[H(P_1) + H(P_2)]$  (see also [4]).

## Results

Both in their spatial and social behaviour, individuals are constantly balancing a trade-off between the exploitation of familiar options (such as returning to a favourite restaurant or spending time with an old friend) and the exploration of new opportunities (such as visiting a new bar or going on a first date) [78]. We adopt this exploration-exploitation perspective to analyse the relationship between social and spatial strategies in our dataset [16].

We quantify the propensity for exploration and exploitation within each individual,  $i$ , using the metrics reported in Table 3, Fig. 1 and described in section ‘Methods’. We focus on two aspects of exploitation, (i) *diversity*, characterising how diverse individuals’ routine are, and (ii) *evolution*, characterising the tendency to change exploited locations and friends over time.

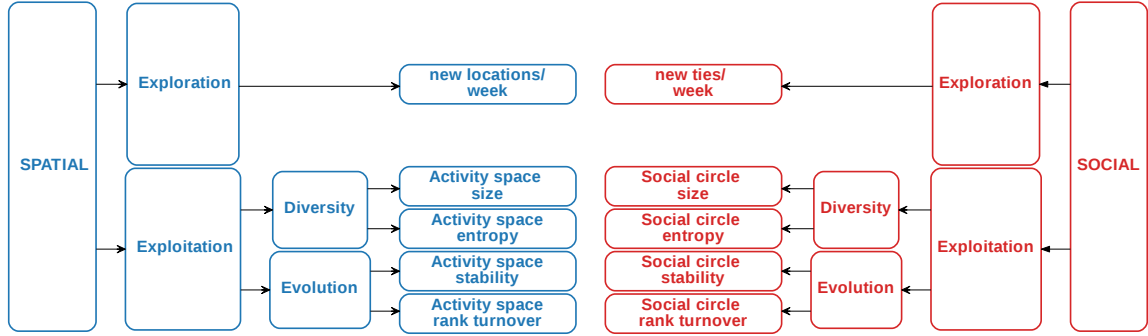

Figure 1: Schematic description of our framework.

	Exploration	Exploitation: Diversity	Exploitation: Evolution
Spatial	New loc./week, $n_{loc}$	Activity space size, $C$ Activity space entropy, $H_{AS}$	Activity space stability, $J_{AS}$ Activity space rank turnover, $R_{AS}$
Social	New ties/week, $n_{tie}$	Social circle size, $k$ Social circle entropy, $H_{SC}$	Social circle stability, $J_{SC}$ Social circle rank turnover, $R_{SC}$

Table 3: Metrics characterising social and spatial behaviour. The metrics are defined in section *Methods*

**Exploration and exploitation are persistent in time.** First, we verify that individual behaviour is persistent in time. For all the aforementioned measures, we compare the individual self-variation across time  $d_{self}(i)$  with a reference difference  $d_{ref}(i, j)$  between individuals  $i$  and  $j$ . In the case of the activity space size, for example, self-variation is measured as  $d_{self} = \langle |C(i, t) - C(i, t - T)| \rangle$ , where  $\langle \cdot \rangle$  is the average across time and  $T = 20$  weeks (see Supplementary Material for  $T = 30$ ); the reference difference is computed as  $d_{ref}(i, j) = |\langle C(i, t) \rangle - \langle C(j, t) \rangle|$ . If  $d_{self}(i) < d_{ref}(i, j)$  for most  $j$ , we can conclude that for individual  $i$ , fluctuations of the activity space size are negligible compared to the difference with other individuals. The same procedure is followed for all metrics with an adjustment in the case of entropies: The persistence of the entropy  $H_{AS}$  is verified by comparing the Janson-Shannon divergences  $d_{self} = JSD(AS(i, t), AS(i, t - T))$  and  $d_{ref} = JSD(AS(i, t), AS(j, t))$ . The same method was used for  $H_{SC}$  (see Methods and [4]).

Results from the CNS dataset reported in Table 4 show that for all metrics  $d_{self}(i) < d_{ref}(i, j)$  holds in more than 99% of cases on average (MDC: 97%, see Supplementary Material Table S1). Moreover, the average self-variation across the population  $\bar{d}_{self}$  is consistent with  $\bar{d}_{self} = 0$  within errors, and  $\bar{d}_{self}$

significantly smaller than the average reference difference  $\overline{d_{ref}}$  (see Tables 4 and S1 in Supplementary Material).

	$\overline{d_{self}}$	$\overline{d_{ref}}$	$\overline{d_{self}(i) < d_{ref}(i, j)}$
Social circle size, $k$	$0.04 \pm 0.09$	$12 \pm 5$	99%
Activity space size, $C$	$0.04 \pm 0.07$	$7 \pm 3$	99%
New locations/week, $n_{loc}$	$0.05 \pm 0.10$	$0.9 \pm 0.5$	96%
New ties/week, $n_{tie}$	$0.10 \pm 0.17$	$1 \pm 1$	95%
Social circle entropy, $H_{SC}$	$0.002 \pm 0.007$	$0.7 \pm 0.2$	99%
Activity space entropy, $H_{AS}$	$0.002 \pm 0.005$	$0.4 \pm 0.1$	99%
Social circle stability, $J_{SC}$	$(9 \pm 22) \cdot 10^{-4}$	$0.13 \pm 0.05$	100%
Activity space stability, $J_{AS}$	$(9 \pm 26) \cdot 10^{-4}$	$0.10 \pm 0.04$	99%
Social circle rank turnover, $R_{SC}$	$0.05 \pm 0.39$	$2 \pm 1$	99%
Activity space rank turnover, $R_{AS}$	$0.04 \pm 0.10$	$2 \pm 1$	99%

Table 4: **CNS dataset: Persistence of social and spatial behaviour.** For each of the social and spatial metrics,  $\overline{d_{self}}$  is the average self-distance and  $\overline{d_{ref}}$  is the reference distance between an individual and all others, averaged across individuals. The third column reports the fraction of cases where  $\overline{d_{self}(i) < d_{ref}(i, j)}$ , averaged across the population.

These results extend previous findings [4, 16] and suggest that each individual is characterised by a distinctive socio-spatial behaviour captured by the ensemble of these metrics averaged across time. In fact, these averages are heterogeneously distributed across the samples considered (see Fig. 2).

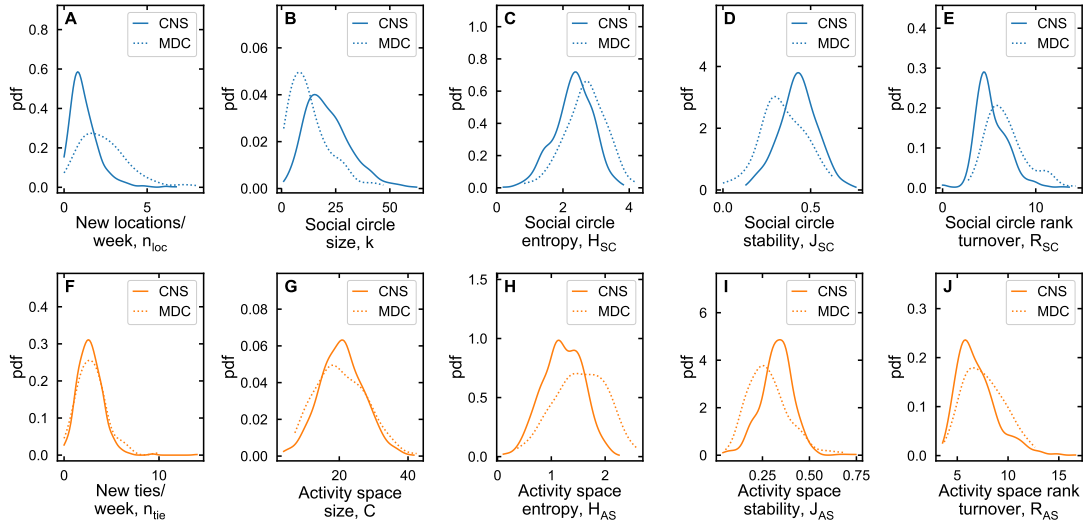

Figure 2: Distribution of social (above line) and spatial (bottom line) metrics for the CNS and MDC datasets.

**Exploration and exploitation are correlated in the social and spatial domain.** A natural way to test the interdependency between social and spatial behaviours is measuring the correlation between a given social metric and a corresponding spatial one. We find positive and significant correlations for all metrics and datasets (see Figs. 3 and S1 in Supplementary Material).

We find that individuals with high propensity to explore new locations are also more keen on exploring social opportunities (see Fig. 3A). Those with diverse mobility routine are also likely to have a

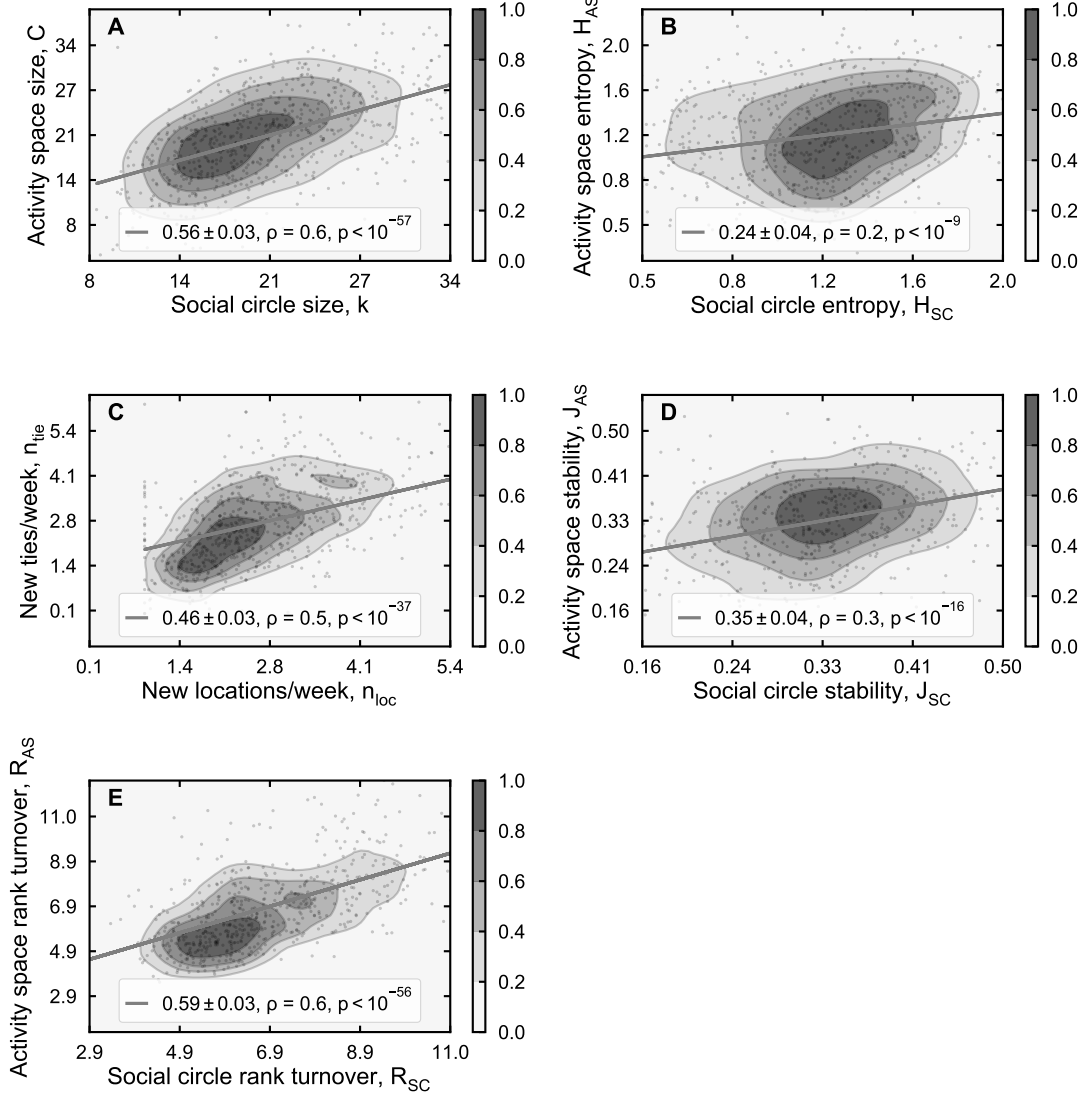

Figure 3: **CNS dataset: correlation between the four dimensions of social and spatial behaviour.** (A) Activity space vs social circle size. (B) Activity space vs social circle composition measured as their entropy. (C) Average number of new locations vs new ties per week. (D) Stability of the activity space vs the stability of the social circle measured as the Jaccard similarity between their composition in consecutive time-windows. (E) Rank turnover of the activity space vs the rank turnover of the social circle. Coloured filled areas correspond to cumulative probabilities estimated via Gaussian Kernel Density estimations. Grey lines correspond to linear fit with angular coefficient  $b$  reported in the legend. The Pearson correlation coefficient, with corresponding p-value, is reported in the legend.

correspondingly large social circle (see Fig. 3B), and those that often replace social ties, have also an unstable set of favourite locations (see Fig. 3C and D).

We verify that the observed correlations are not spurious by performing multiple regression analyses that control for other possible sources of variation: gender, age, and time coverage (the average time an individual position is known). We implement five multiple linear regression models M1, M2, M3, M4 and M5. Each regression model predicts a given spatial metric (the activity space size  $C$ , the activity space entropy  $H_{AS}$ , the number of new locations/week  $n_{loc}$ , the activity space stability  $J_{AS}$  and the rank turnover  $R_{AS}$ ) using the corresponding social metric and the control variables (age, gender and time coverage) as regressors. The relative importance of each regressor is assessed using the *LMG* [79] method.

Results obtained via weighted least square regression (see Tables 5 and S2 in Supplementary Material) reveal that the social metrics are significant predictors for spatial metrics (p value > 0.01 in all cases except for M4 in the MDC dataset), and they typically have more importance than factors such as gender, time, coverage and age group (see Fig. 4).

Among the control variables, gender is a significant predictor of spatial behaviour in the CNS dataset: Females display higher level of routine diversity and propensity towards exploration, in accordance with [80]. Time coverage, measuring the fraction of time an individual position is known, plays a significant role in explaining spatial entropy and activity space stability, since individuals who spend long time in the same place (or leave their phone in the same place) are more easily geo-localised. Age differences are not present within the sample of students participating in the CNS study, and they are not estimated to be relevant with respect to spatial behaviour in the MDC study.

**We do not identify distinct classes of individuals.** A natural question is whether or not, in the samples considered, there is evidence for distinct classes of individuals based on their socio-spatial behaviour [5, 14]. We approach this problem by reducing the set of metrics to a smaller number of uncorrelated variables by applying Principal Component Analysis [81, 82].

In both datasets, we find that a single predominant component explains  $\sim 40\%$  of the differences between individuals (see Table 6). This dimension is dominated by the metrics quantifying exploration and routine diversity (see Table 7). This suggests that individuals with higher exploration propensity tend to have larger social circle and more diverse spatial routine, while those who explore less also have less diverse routines.

The second principal component, which accounts for  $\sim 15\%$  of the total variation, is dominated by the effects of evolving routines over long time scales (see Table 7). We consider the two predominant components to reduce the effects of noise and we test the hypothesis that there exists different classes of individuals using the gap statistic method [83]. The test does not support the existence of more than one class of individuals.

**The big-five personality traits partly explain spatial and social behaviour.** We verify if the differences between individuals can be explained by the Big five personality traits model [75], typically used to describe social and emotional life (see Table 8). We build two multiple linear regression models that use the Big five personality traits as regressors and one of the principal components describing socio-spatial behaviour as target. Results, shown in Table 9, show that three personality traits, neuroticism, openness and extraversion, are relevant predictors for socio-spatial behaviour. In particular, extraversion is the most important predictor of the first principal component: it characterises the tendency to diversify routine and to explore opportunities. Neuroticism and openness explain instead the second principal component, which characterises the tendency to change routine over time (see also Fig. 5). We verify that the same analysis performed considering only the spatial metrics leads to similar results (see Tables 10, 11, 12 and Fig. 6). All the result presented above hold when choosing a time-window with length  $T = 30$  weeks (see Supplementary Material, section 2).

## Discussion

Using high resolution data from two large scale studies, we have investigated the connection between social and spatial behaviour for the first time. We have shown that, in both domains, individuals balance the trade-off between exploring new opportunities and exploiting known options in a distinctive and persistent manner. We have found that, to a significant extent, individuals adopt a similar strategy in the social and spatial sphere. These strategies are heterogeneous across the two samples considered, and there is no evidence suggesting that there exist distinct classes of individuals. Finally, we have shown that the big five personality traits explain related aspects of both social and spatial behaviour. In particular, we have found that extraverted individuals are more explorative and have diverse routines in both the social and the spatial sphere while neuroticism and openness associate with high level of routine instability in the social and spatial domain.

Our findings confirm the usefulness of mobile phone data to study the connections between behaviour and personality [29, 40, 44, 84–86]. The results are in line with previous findings on the relation between personality and social behaviour: extraversion correlates with social network size [18, 41, 43], openness to experience to social network turnover [29] and neuroticism does not correlate with social network size [11]. Finally, our findings establish a relation between personality and spatial behaviour, validating

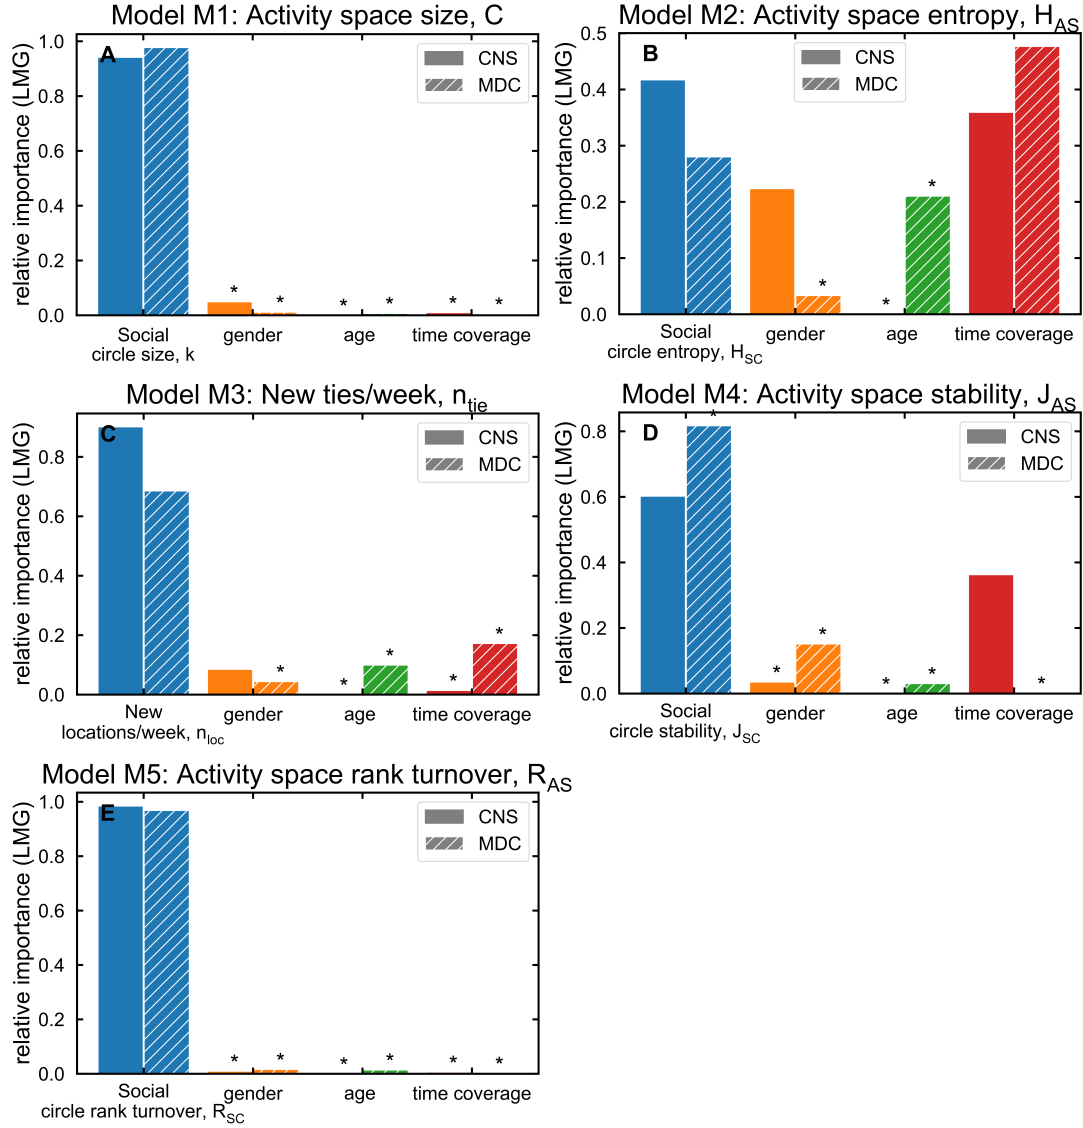

Figure 4: **Relative importance of regressors** LMG of each regressor computed using the Lindeman, Merenda and Gold method [79] for models M1 (A), M2 (B), M3 (C), M4 (D) and M5 (D). Plain bars show results for the CNS dataset, dashed bars for the MDC dataset. Variables that are not significant in the regression model are marked with \*.

$[R^2 = 0.36, F = 108.31, p_F = 0.0]$				

Table 5: **Linear regression models for the CNS dataset.** For each model, we show the coefficients (coeff) calculated by the regression model, the probability (p val) that the variable is not relevant, and the relative importance (LMG) of each regressor computed using the Lindeman, Merenda and Gold method [79]. Gender is a binary variable taking value 1 for females and 2 for males. For this dataset, age is not relevant as all participants have similar age. For each model, we report the  $R^2$  goodness of fit, the  $F$  – test statistics with the corresponding p-value  $p_F$ . W

the theories suggesting that spatial choices are partially dictated by personality dispositions [15] and that a single set of personality traits underlies all aspect of a person’s behaviour [2, 3]. The individual

Activity space entropy, $H_{AS}$	0.38	-0.16	0.30	-0.07
Social circle stability, $J_{SC}$	-0.16	-0.46	0.07	-0.72
Activity space stability, $J_{AS}$	-0.10	-0.49	-0.12	-0.51
Social circle rank turnover, $R_{SC}$	-0.20	0.28	-0.33	0.10
Activity space rank turnover, $R_{AS}$	-0.30	0.44	-0.38	0.17

Table 7: **Principal Components.** The weight of each metric in the first two principal components, for both datasets.

Trait	Related Adjectives
Extraversion	Active, Assertive, Energetic, Enthusiastic, Outgoing, Talkative
Agreeableness	Appreciative, Forgiving, Generous, Kind, Sympathetic
Conscientiousness	Efficient, Organised, Planful, Reliable, Responsible, Thorough
Neuroticism	Anxious, Self-pitying, Tense, Touchy, Unstable, Worrying
Openness to Experience	Artistic, Curious, Imaginative, Insightful, Original, Wide Interests

Table 8: The Big-Five traits and examples of adjectives describing them [88]

characterisation of spatial behaviour is also fundamental to develop conceptual [55] and predictive [87] models of travel behaviour accounting for individual-level differences.

	PC 0 $R^2 = 0.17, F = 21.40, p_F = 0.0$			PC 1 $R^2 = 0.03, F = 3.64, p_F = 0.0$		
	coeff	p val	LMG	coeff	p val	LMG
extraversion	$0.85 \pm 0.09$	$< 10^{-19}$	0.85	$0.12 \pm 0.06$	0.05	0.14
openness	$-0.17 \pm 0.08$	0.03	0.02	$0.13 \pm 0.06$	0.02	0.33
neuroticism	$0.25 \pm 0.09$	0.004	0.04	$0.15 \pm 0.06$	0.02	0.3
agreeableness	$0.11 \pm 0.08$	0.2	0.04	$-0.07 \pm 0.06$	0.2	0.12
conscientiousness	$0.06 \pm 0.08$	0.4	0.04	$-0.07 \pm 0.06$	0.2	0.11

Table 9: **Extraversion, openness, and neuroticism explain socio-spatial behaviour.** The result of a multiple linear regression explaining principal components of socio-spatial data (see Table 7). The value of each coefficient (coeff) is reported together with the probability (p val) that the coefficient is not relevant for the model. The relative importance of each coefficient (LMG) is computed using the LMG method [79].

Table 12: **Extraversion, openness, and neuroticism explain spatial behaviour.** The result of a multiple linear regression explaining principal components of spatial data (see Table 7). The value of each coefficient (coeff) is reported together with the probability (p val) that the coefficient is not relevant for the model. The relative importance of each coefficient (LMG) is computed using the LMG method [79].

## Competing interests

The authors declare that they have no competing interests.

## Author's contributions

LA, SL and AB designed the study; LA performed the analysis; LA, SL and AB analysed the results; LA, SL and AB wrote the paper.

## Acknowledgements

This work was supported by the Danish Council for Independent Research (“Microdynamics of influence in social systems”, grant id. 4184-00556, SL is PI). Portions of the research in this paper used the MDC Database made available by Idiap Research Institute, Switzerland and owned by Nokia.

## List of Abbreviations

CNS: Copenhagen Networks Study  
MDC: (Lausanne) Mobile Data Challenge  
GSM: Global System for Mobile Communications  
JSD: Jensen-Shannon divergence  
LMG: Lindeman, Merenda and Gold

# Supplementary Material for Individual mobility and social behaviour: Two sides of the same coin

## 1 Results obtained with the MDC dataset

Tables S1, S2 and Fig. S1 report the results of the persistence analysis, the multiple regression analysis, and the correlation analysis for the MDC dataset.

	$\overline{d_{self}}$	$\overline{d_{ref}}$	$\overline{d_{self}(i) < d_{ref}(i, j)}$
Social circle size, $k$	$0.05 \pm 0.13$	$10 \pm 5$	97%
Activity space size, $C$	$0.07 \pm 0.12$	$8 \pm 3$	97%
New locations/week, $n_{loc}$	$0.2 \pm 0.3$	$2 \pm 1$	91%
New ties/week, $n_{tie}$	$0.2 \pm 0.6$	$2 \pm 1$	90%
Social circle entropy, $H_{SC}$	$0.006 \pm 0.014$	$0.7 \pm 0.3$	97%
Activity space entropy, $H_{AS}$	$0.004 \pm 0.008$	$0.5 \pm 0.2$	97%
Social circle stability, $J_{SC}$	$0.002 \pm 0.005$	$0.15 \pm 0.05$	99%
Activity space stability, $J_{AS}$	$0.002 \pm 0.004$	$0.12 \pm 0.05$	99%
Social circle rank turnover, $R_{SC}$	$0.07 \pm 0.15$	$2 \pm 1$	98%
Activity space rank turnover, $R_{AS}$	$0.2 \pm 0.6$	$2 \pm 1$	97%

Table S1: **MDC dataset: Persistence of social and spatial behaviour.** For each of the social and spatial metrics,  $\overline{d_{self}}$  is the average self-distance and  $\overline{d_{ref}}$  is the reference distance between an individual and all others, averaged across individuals. The third column reports the fraction of cases where  $\overline{d_{self}(i) < d_{ref}(i, j)}$ , averaged across the population.

<b>Model M1: Activity space size, <math>C</math></b>		coeff	p val	LMG
Social circle size, $k$		$5 \pm 1$	$< 10^{-11}$	0.98

time coverage		$-0.06 \pm 0.15$	0.7	0.0
$[R^2 = 0.55, F = 27.24, p_F = 0.0]$				

Table S2: **Linear regression models for the MDC dataset.** For each model, we report the  $R^2$  goodness of fit, the  $F$ -test statistics with the corresponding p-value  $p_F$ . We show the coefficients (coeff) calculated by the regression model, the probability (p val) that the variable is not relevant, and the relative importance (LMG) of each regressor computed using the Lindeman, Merenda and Gold method. Gender is a binary variable taking value 1 for females and 2 for males.

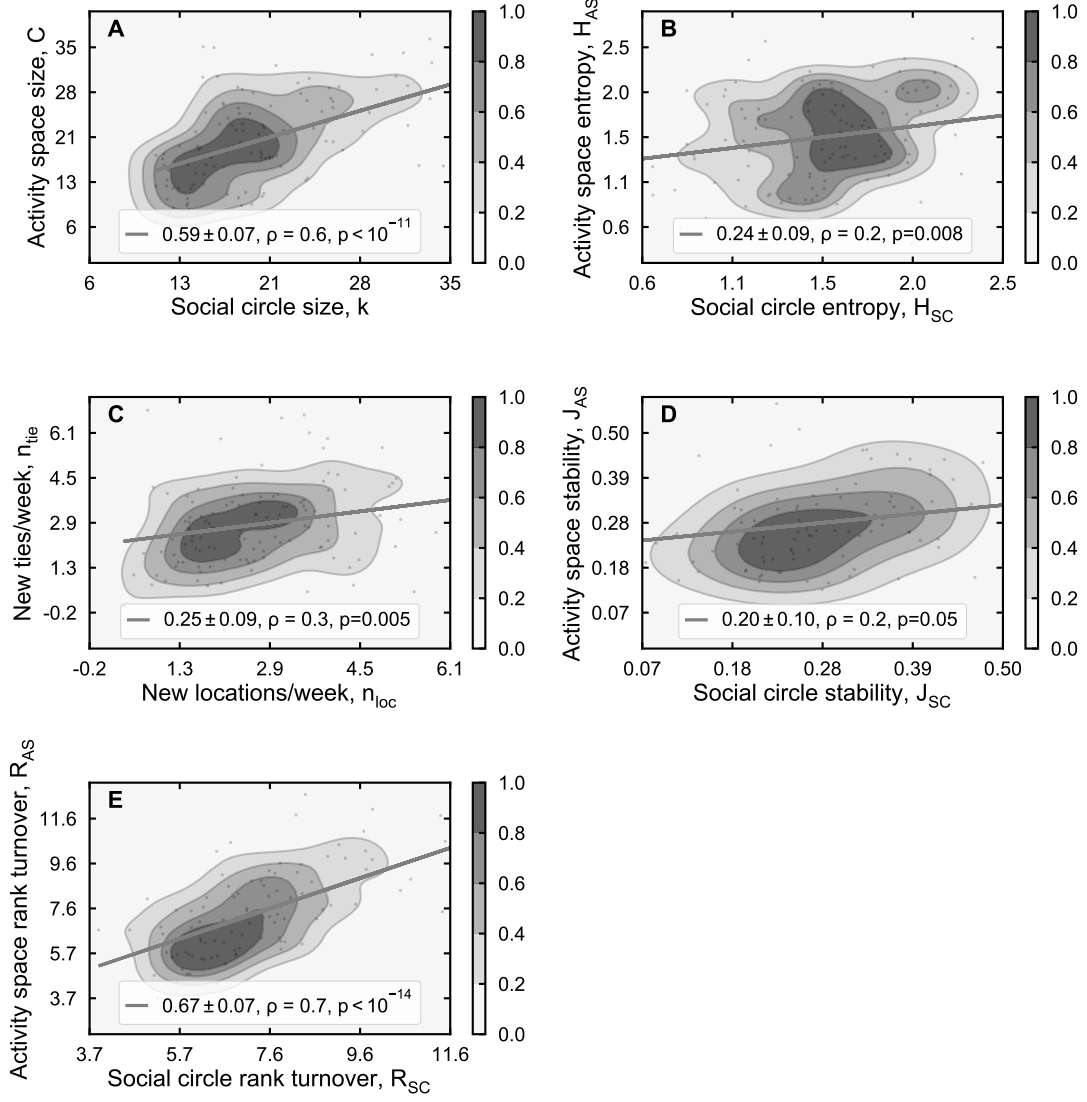

Figure S1: **MDC dataset: correlation between the four dimensions of social and spatial behaviour.** (A) Activity space vs social circle size. (B) Activity space vs social circle composition measured as their entropy. (C) Average number of new locations vs new ties per week. (D) Stability of the activity space vs the stability of the social circle measured as the Jaccard similarity between their composition in consecutive time-windows. (E) Rank turnover of the activity space vs the rank turnover of the social circle. Coloured filled areas correspond to cumulative probabilities estimated via Gaussian Kernel Density estimations. Grey lines correspond to linear fit with angular coefficient  $b$  reported in the legend. The Pearson correlation coefficient, with corresponding p-value, is reported in the legend.

## 2 Results obtained with other windows

Figs. S3, S5, S5, S6 and Tables S3, S4, S5, S6, S7, S8, S9, S10 report the results obtained choosing a time-window with length  $T = 30$  weeks (see main manuscript, section ‘Methods’).

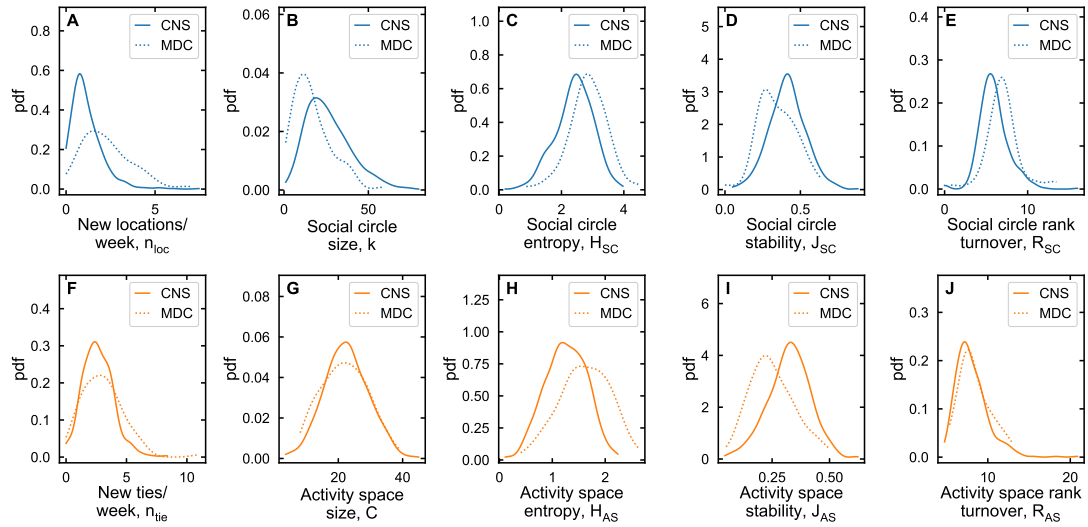

Figure S2:  $T=30$ , Distribution of social (above line) and spatial (bottom line) metrics for the CNS and MDC datasets.

Figure S3: **T=30, CNS dataset: correlation between the four dimensions of social and spatial behaviour.** (A) Activity space vs social circle size. (B) Activity space vs social circle composition measured as their entropy. (C) Average number of new locations vs new ties per week. (D) Stability of the activity space vs the stability of the social circle measured as the Jaccard similarity between their composition in consecutive time-windows. (E) Rank turnover of the activity space vs the rank turnover of the social circle. Coloured filled areas correspond to cumulative probabilities estimated via Gaussian Kernel Density estimations. Grey lines correspond to linear fit with angular coefficient  $b$  reported in the legend. The Pearson correlation coefficient, with corresponding p-value, is reported in the legend.

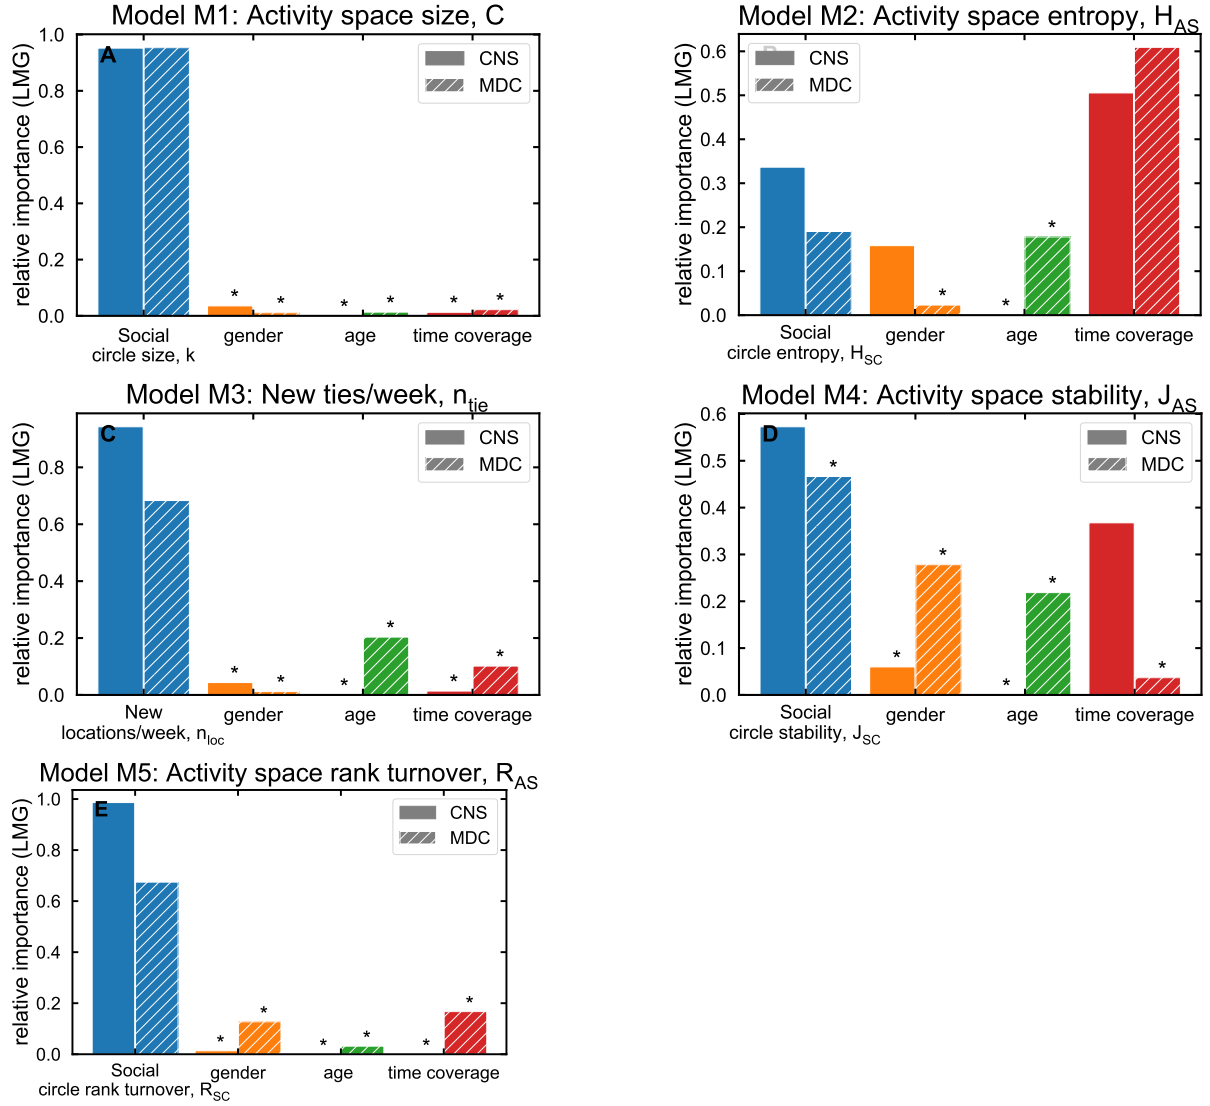

Figure S4: **T=30, Relative importance of regressors** LMG of each regressor computed using the Lindeman, Merenda and Gold method for models M1 (A), M2 (B), M3 (C), M4 (D) and M5 (E). Plain bars show results for the CNS dataset, dashed bars for the MDC dataset. Variables that are not significant in the regression model are marked with \*.

Figure S5: **T=30, Relative importance of personality traits for socio-spatial behaviour LMG** of each regressor computed using the Lindeman, Merenda and Gold method for the multiple regression model of the principal components (table S7).

Figure S6: **T=30, Relative importance of personality traits for spatial behaviour LMG** of each regressor computed using the Lindeman, Merenda and Gold method for the multiple regression model of the principal components (table S10).

	$\overline{d_{self}}$	$\overline{d_{ref}}$	$\overline{d_{self}(i) < d_{ref}(i, j)}$
Social circle size, $k$	$0.04 \pm 0.13$	$15 \pm 6$	100%
Activity space size, $C$	$0.04 \pm 0.07$	$8 \pm 3$	99%
New locations/week, $n_{loc}$	$0.06 \pm 0.12$	$0.9 \pm 0.5$	96%
New ties/week, $n_{tie}$	$0.1 \pm 0.2$	$1 \pm 1$	95%
Social circle entropy, $H_{SC}$	$0.002 \pm 0.005$	$0.7 \pm 0.3$	99%
Activity space entropy, $H_{AS}$	$0.002 \pm 0.006$	$0.4 \pm 0.1$	99%
