EXTENDED ABSTRACT

A creative process is “*the sequence of thoughts and actions that lead to a novel, adaptive production*” (Lubart 2001, 295). Narratives of the creative process can enhance the perceived quality of a product and stimulate inferences on the creator’s ability to produce additional high-quality ideas and outputs (Baas et al. 2015; Mourgues et al. 2016), improve empathy between creators and their audiences (Davis 1983; Friestad and Wright 1994), and increase *process transparency* (Buell and Norton 2011; Buell, Kim and Tsay 2017). These narratives can emphasize either the experience of *insight* (Schooler, Fallshore, and Fiore 1995) – the sudden, dream-like, spontaneous and illuminating experience facilitating the emergence of new ideas—or the application of *effort* (Lucas and Nordgren 2015) – the methodical, planned, and rational stage in which ideas are organized and transformed into a new product.

People hold beliefs on how creative products are generated (e.g., Sternberg 1985; Runco and Bahleda 1986; O’Connor, Nemeth and Akutsu 2013), and these beliefs can influence product evaluations due to reliance on stereotypical knowledge and heuristics (Sternberg 1985; Levy, Stroessner, and Dweck 1998). We maintain that an insight-based narrative of the creative process (Rothenberg 1970; Kasof 1995) has greater fit with artistic domains, whereas an effort-based narrative of the creative process has greater fit with scientific domains (Lucas and Nordgren 2015). Because lay beliefs influence evaluations of creative products (Baas et al. 2015; Sternberg 1985), we expect artistic products to receive better evaluations when their creative process is described through insight-based narratives rather than effort-based narratives and that the opposite pattern holds for scientific products.

We also expect experts to be more analytical in processing information and less sensitive to heuristics, to own to a higher extent the meta-cognitive skills necessary to evaluate others’ level of ability (Kruger and Dunning 1999), and to be more receptive towards effort-based narratives of the creative process (Ericsson, Krampe, and Tesch-Romer 1993; Ericsson, Prietula, and Cokely 2007), thus to respond relatively more favorably to information on central and concrete – rather than ephemeral and transient – factors characterizing the creative process. Six studies support the proposed conceptual framework and the existence of optimal narratives for the promotion of artistic and scientific products to different audiences.

Study 1 verified the existence of associations between an insight-based creative process and artistic domains, and between an effort-based creative process and scientific domains. Participants read the descriptions of twelve new successful artistic works and scientific works and rated the extents to which they were the outcome of insight and effort. Each art work received higher insight ratings than effort ratings, and each science work received higher effort ratings than insight ratings. Furthermore, all art works received higher insight ratings than all science works, and all scientific works received higher effort ratings than all art works.

Studies 2A and 2B investigated whether describing a creative process using insight- vs. effort-based narratives affects evaluations of new products in artistic and scientific domains, respectively. Participants in Study 2A read an interview in which a band described the creative

process leading to their last song either as insight-based or effort-based. Afterwards, they listened to a 45-second excerpt of the song. Participants evaluated the song more favorably and were willing to pay more, when it was presented through insight-based (vs. effort-based) narratives. In study 2B we measured intentions to fund a Kickstarter project based on scientific research that was presented through insight- vs. effort-based narratives of the creative process. When it was presented through effort-based narrative, the project was considered (marginally) more likely to reach the fund-raising goal and participants allocated more funds to it than when it was presented through an insight-based narrative.

Studies 3A and 3B replicated studies 2A and 2B but also tested the proposed fit mechanism, as well as the role of expertise, in the artistic and scientific domain, respectively. Participants in Study 3A evaluated the song from Study 2A more favorably and were willing to pay more for it when they read it was the outcome of insight than effort. The perceived fit between the creative process narrative and the image of the creator mediated both effects. In addition, an insight-based creative process produced more favorable evaluations of an artistic product, but this effect was attenuated as recipients' expertise increased. Participants in Study 3B evaluated the project from Study 2B as (marginally) more likely to reach the fund-raising goal and assigned more funds to it when it was described as effort-based than as insight-based. Also in this case, the perceived fit between the type of creative process and the work mediated both effects. In line with our prediction, expertise did not interact with the type of narrative of the creative process, as both experts and non-experts prefer effort-based narratives. However, the perceived fit between the nature of the creative process and the image of the creator only mediated the effect when participants' expertise was low to average.

In Study 4, participants read descriptions of a new product presented as either artistic or scientific, and as the outcome of either an insight- or an effort-based creative process. When the product was described as artistic, participants evaluated it more favorably and were willing to pay more for it, if they read it was the outcome of insight rather than of effort. When the product was presented as scientific product, the opposite pattern was observed.

This research clarifies that beliefs on the nature of the creative process depend on the domain of the creative output, and that the most effective communication strategy regarding the creative process leading to a product depends critically on both the nature (scientific or artistic) of the product, and the level of expertise of the audience targeted.
